

NAME

autoinst – wrapper around the LCDF TypeTools, for installing and using OpenType fonts in (La)TeX.

SYNOPSIS

autoinst [*options*] **fontfile(s)**

DESCRIPTION

Eddie Kohler’s *LCDF TypeTools* are superb tools for installing OpenType fonts in LaTeX, but they can be hard to use: they need many, often long, command lines and don’t generate the *fd* and *sty* files LaTeX needs. **autoinst** simplifies the use of the *TypeTools* for font installation by generating and executing all commands for *otf*/*otfm* and by creating and installing all necessary *fd* and *sty* files.

Given a family of font files (in *otf* or *ttf* format), **autoinst** will create several LaTeX font families:

- Four text families (with lining and oldstyle digits, each in both tabular and proportional variants), all with the following shapes:

<i>n</i>	Roman (i.e., upright) text
<i>it, sl</i>	Italic and slanted (sometimes called oblique) text
<i>sc</i>	Small caps
<i>sw</i>	Swash
<i>tl</i>	Titling shape. Meant for all-caps text; letterspacing and the positioning of punctuation characters have been adjusted to suit all-caps text. (This shape is only generated for the families with lining digits, since old-style digits make no sense with all-caps text.)
<i>scit, scsl</i>	Italic and slanted small caps
<i>nw</i>	“Upright swash”; usually roman text with a few “oldstyle” ligatures like ct, sp and st.
<i>tlit, tisl</i>	Italic and slanted titling text
- For each T1-encoded text family: a family of TS1-encoded symbol fonts, in roman, italic and slanted shapes.
- Families with superiors, inferiors, numerators and denominators, in roman, italic and slanted shapes.
- An ornament family, also in roman, italic and slanted shapes.

Of course, if your fonts don’t contain italics, oldstyle digits, small caps etc., the corresponding shapes and families are not created. In addition, the creation of most families and shapes can be controlled by the user (see “COMMAND-LINE OPTIONS” below).

These families use the *FontPro* project’s naming scheme: *<FontFamily>-<Suffix>*, where *<Suffix>* is:

<i>LF</i>	proportional (i.e., figures have varying widths) lining figures
<i>TLF</i>	tabular (i.e., all figures have the same width) lining figures
<i>OsF</i>	proportional oldstyle figures
<i>TOsF</i>	tabular oldstyle figures
<i>Sup</i>	superior characters (note that most fonts have only an incomplete set of superior characters: digits, some punctuation and the letters <i>abdeilmnorst</i> ; normal forms are used for other characters)
<i>Inf</i>	inferior characters; usually only digits and some punctuation, normal forms for other characters
<i>Orn</i>	ornaments
<i>Numr</i>	numerators
<i>Dnom</i>	denominators

The individual fonts are named *<FontName>-<suffix>-<shape>-<enc>*, where *<suffix>* is the same as above (but in lowercase), *<shape>* is either empty, “sc”, “swash” or “titling”, and *<enc>* is the encoding (also in lowercase). A typical name in this scheme would be “FiraSans-Light-osf-sc-ly1”.

On the choice of text encoding

By default, **autoinst** generates text fonts with OT1, T1 and LY1 encodings, and the generated style files use LY1 as the default text encoding. LY1 has been chosen over T1 because it has some empty slots to accommodate the additional ligatures found in many OpenType fonts. Other encodings can be chosen using the `-encoding` option (see “COMMAND-LINE OPTIONS” below).

Using the fonts in your LaTeX documents

autoinst generates a style file for using the fonts in LaTeX documents, named `<FontFamily>.sty`. This style file also takes care of loading the *fontenc* and *textcomp* packages. To use the fonts, add the command `\usepackage{<FontFamily>}` to the preamble of your document.

This style file defines a number of options:

`lining, oldstyle, tabular, proportional`

Choose which figure style to use. The defaults are “oldstyle” and “proportional” (if available).

`scale=<number>`

Scale the font by a factor of `<number>`. E.g., to increase the size of the font by 5%, use `\usepackage[scale=1.05]{<FontFamily>}`. May also be spelled `scaled`.

This option is only available when you have the *xkeyval* package installed.

`light, medium, book, text, regular`

Select the weight that LaTeX will use as the “regular” weight; the default is `regular`.

`heavy, ultrablack, extrablack, black, ultrabold, extrabold, demibold, semibold, bold`

Select the weight that LaTeX will use as the “bold” weight; the default is `bold`.

The previous two groups of options will only work if you have the *mweights* package installed.

The style file will also try to load the *fontaxes* package (available on CTAN), which gives easy access to various font shapes and styles. Using the machinery set up by *fontaxes*, the generated style file defines a number of commands (which take the text to be typeset as argument) and declarations (which don’t take arguments, but affect all text up to the end of the current group) to access titling, superior and inferior characters:

DECLARATION	COMMAND	SHORT FORM OF COMMAND
<code>\tlshape</code>	<code>\texttitling</code>	<code>\textttl</code>
<code>\sufigures</code>	<code>\textsuperior</code>	<code>\textsu</code>
<code>\infigures</code>	<code>\textinferior</code>	<code>\textin</code>

In addition, the `\swshape` and `\textsw` commands are redefined to place swash on *fontaxes*’ secondary shape axis (*fontaxes* places it on the primary shape axis) to make them behave properly when nested, so that `\swshape\upshape` will give upright swash.

There are no commands for accessing the numerator and denominator fonts; these can be selected using *fontaxes*’ standard commands, e.g., `\fontfigurestyle{numerator}\selectfont`.

The style file also provides a command `\ornament{<number>}`, where `<number>` is a number from 0 to the total number of ornaments minus one. Ornaments are always typeset using the current family, series and shape. A list of all ornaments in a font can be created by running LaTeX on the file *nfssfont.tex* (part of a standard LaTeX installation) and supplying the name of the ornament font.

To access ornament glyphs, **autoinst** creates a font-specific encoding file `<FontFamily>_orn.enc`, but only if that file doesn’t yet exist in the current directory. This is a deliberate feature that allows you to provide your own encoding vector, e.g. if your fonts use non-standard glyph names for ornaments.

These commands are only generated for existing shapes and number styles; no commands are generated for shapes and styles that don’t exist, or whose generation was turned off by the user. Also these commands are built on top of *fontaxes*, so if that package cannot be found, you’re limited to using the lower-level commands from standard NFSS (`\fontfamily`, `\fontseries`, `\fontshape` etc.).

Also, some OpenType fonts may lead to *pl* and *vpl* files that are too big for MiKTeX's *plotf* and *vptovf*; the versions that come with W32TeX (<http://www.w32tex.org>) and TeXLive (<http://tug.org/texlive>) don't seem to have this problem.

COMMAND-LINE OPTIONS

autoinst tries hard to do The Right Thing (TM) by default, so you usually won't really need these options; but most aspects of its operation can be fine-tuned if you want to.

You may use either one or two dashes before options, and option names may be shortened to a unique prefix (e.g., **-encoding** may be abbreviated to **-enc** or even **-en**, but **-e** is ambiguous (it may mean either **-encoding** or **-extra**)).

-dryrun

Don't generate any output files; only parse the input fonts and create *autoinst.log* showing which fonts would have been generated.

-encoding=encoding[,encoding]

Generate the specified encoding(s) for the text fonts. The default is "OT1,T1,LY1". For each encoding, a file *<encoding>.enc* (in all *lowercase*!) should be somewhere where *otfotfm* can find it. Suitable encoding files for OT1, T1/TS1, LY1, LGR and T2A/B/C come with **autoinst**. (These files are called *fontools_ot1.enc* etc. to avoid name clashes with other packages; the "fontools_" prefix may be omitted.)

Multiple text encodings can be specified as a comma-separated list: **-encoding=OT1,T1** (without spaces!). The generated style file passes these encodings to *fontenc* in the specified order, so the last one will become the default text encoding for your documents.

-ts1 / -nots1

Control the creation of TS1-encoded fonts. The default is **-ts1** if the text encodings (see **-encoding** above) include T1, **-nots1** otherwise.

-sanserif

Install the font as a sanserif font, accessed via `\sffamily` and `\textsf`. The generated style file redefines `\familydefault`, so including it will still make this font the default text font.

-typewriter

Install the font as a typewriter font, accessed via `\ttfamily` and `\texttt`. The generated style file redefines `\familydefault`, so including it will still make this font the default text font.

-lining / -nolining

Control the creation of fonts with lining figures. The default is **-lining**.

-oldstyle / -nooldstyle

Control the creation of fonts with oldstyle figures. The default is **-oldstyle**.

-proportional / -noproportional

Control the creation of fonts with proportional figures. The default is **-proportional**.

-tabular / -notabular

Control the creation of fonts with tabular figures. The default is **-tabular**.

-smallcaps / -nosmallcaps

Control the creation of small caps fonts. The default is **-smallcaps**.

-swash / -noswash

Control the creation of swash fonts. The default is **-swash**.

-titling / -notitling

Control the creation of titling fonts. The default is **-titling**.

-superiors / -nosuperiors

Control the creation of fonts with superior characters. The default is **-superiors**.

-infiors=[*sinf* | *subs* | *dnom*]

The OpenType standard defines several kinds of digits that might be used as inferiors or subscripts: “Scientific Inferiors” (OpenType feature “*sinf*”), “Subscripts” (“*subs*”) and “Denominators” (“*dnom*”). This option allows the user to determine which of these styles **autoinst** should use for the inferior characters. The default is not to create fonts with inferior characters.

*Note that many fonts contain only one (or even none) of these types of inferior characters. If you specify a style of inferiors that isn’t actually present in the font, **autoinst** silently falls back to its default of not creating fonts with inferiors; it doesn’t try to substitute one of the other features.*

-fractions / -nofractions

Control the creation of fonts with numerators and denominators. The default is **-nofractions**.

-ornaments / -noornaments

Control the creation of ornament fonts. The default is **-ornaments**.

-defaultlining / -defaultoldstyle**-defaulttabular / -defaultproportional**

Tell **autoinst** which figure style is the current font family’s default (i.e., which figures you get when you don’t specify any OpenType features).

Don’t use these options unless you are certain you need them! They are only needed for fonts that don’t provide OpenType features for their default figure style; and even in that case, **autoinst**’s default values (**-defaultlining** and **-defaulttabular**) are usually correct.

-nofigurekern

Some fonts provide kerning pairs for tabular figures. This is very probably not what you want (e.g., numbers in tables won’t line up exactly). This option adds extra *--ligkern* options to the commands for *otftotfm* to suppress such kerns. Note that this option leads to very long commands (it adds one hundred *--ligkern* options), which may cause problems on some systems.

-mergewidths / -nomergewidths

Some font families put Condensed and Extended fonts in separate families; this option tells **autoinst** to merge those separate families into the “main” font family. The default is **-nomergewidths**.

-extra=text

Append *text* as extra options to the command lines for *otftotfm*. To prevent *text* from accidentally being interpreted as options to **autoinst**, it should be properly quoted.

-manual

Manual mode. By default, **autoinst** immediately executes all *otftotfm* commands it generates; with the **-manual** option, these commands are instead written to a file *autoinst.bat*. Furthermore it adds the *--pl* option (which tells *otftotfm* to generate human readable/editable *pl* and *vpl* files instead of the default *tfm* and *vf* files) and omits the *--automatic* option (which causes *otftotfm* to leave all generated files in the current directory, rather than install them into your TEXMF tree). Manual mode is meant to enable tweaking the generated commands and post-processing the generated files.

When using this option, run *plotf* and *vptovf* after executing the commands (to convert the *pl* and *vf* files to *tfm* and *vf* format) and move all generated files to their proper destinations.

All following options are only meaningful in automatic mode, and hence ignored in manual mode:

-target=DIRECTORY

Install all generated files into the TEXMF tree at *DIRECTORY*. This option allows the user to override **autoinst**’s default behaviour, which is to search the *\$TEXMFLOCAL* and *\$TEXMFHOME* paths and install all files into subdirectories of the first writable TEXMF tree it finds (or into subdirectories of the current directory, if no writable directory is found).

-vendor=VENDOR**-typeface=TYPEFACE**

These options are equivalent to *otftotfm*’s *--vendor* and *--typeface* options: they change the “vendor” and “typeface” parts of the names of the subdirectories in the TEXMF tree where generated

files will be stored. The default values are “`lcdftools`” and the font’s `FontFamily` name.

Note that these options change *only* directory names, not the names of any generated files.

–updmap / –noupdmap

Control whether or not *updmap* is called after the last call to *otftotfm*. The default is **–updmap**.

SEE ALSO

Eddie Kohler’s **TypeTools** (<http://www.lcdf.org/type>).

Perl can be obtained from <http://www.perl.org>; it is included in most Linux distributions. For Windows, try ActivePerl (<http://www.activestate.com>) or Strawberry Perl (<http://strawberryperl.com>).

XeTeX (<http://www.tug.org/xetex>) and **LuaTeX** (<http://www.luatex.org>) are Unicode-aware TeX engines that can use OpenType fonts directly, without any (La)TeX-specific support files.

The **FontPro** project (<https://github.com/sebschub/FontPro>) offers very complete LaTeX support (even for typesetting maths) for Adobe’s Minion Pro, Myriad Pro and Cronos Pro font families.

RECENT CHANGES

(See the source for the full story, all the way back to 2005.)

2018–08–10 Added encoding files for LGR and T2A/B/C to *fontools*.

2018–03–26 Added the “Text” weight and the *–(no)mergewidths* option. Changed the NFSS codes for “Thin” and “Book” to “i” and “o”, respectively. Tried to improve the documentation.

2018–01–09 Added the “sl” weight for font families (such as Fira Sans) that contain both “Book” and “Regular” weights (reported by Bob Tennent). Added the “Two”, “Four”, “Eight” and “Hair” weights (for Fira Sans).

2017–06–16 Changed the *–inferiors* option from a binary yes-or-no choice to allow the user to choose one of the “sinf”, “subs” and “dnom” features. **autoinst** now always creates a log file.

2017–03–21 Updated the *fontools_otl.enc* encoding file to include the “Lslash” and “Islash” glyphs (thanks to Bob Tennent).
